

# CS I 80: Algorithms and Complexity

Professor: Raghu Meka (raghum@cs)

# Plan for Today

- Logistics
- What is an algorithm?

# Course goals

- **“Algorithmic thinking”**
  - Design and analysis
- **Algorithmic lens: all areas of science**
  - Applications
- **Core design principles and algorithms**

Question **1**

Not yet answered

Marked out of 0.20

Solution of the recurrence  $T(n) = 13 T(n/3) + n^3$  is:

Select one:

- ☐ a.  $O(n^2)$
- ☐ b.  $O(n^3)$
- ☐ c.  $O(n^{(2.67)})$
- ☐ d.  $O(n^{(13/3)})$

ANSWER =

# First algorithm you ever saw/did ...

## Multiplication

**INPUT:** Two  $n$ -digit numbers  $a, b$

**OUTPUT:**  $(a \times b)$  in decimal format.

# First algorithm you ever saw/did ...

## Multiplication

**INPUT:** Two  $n$ -digit numbers  $a, b$

**OUTPUT:**  $(a \times b)$  in decimal format.

How efficient is the previous algorithm?

What is efficiency?

# What is efficiency?

Answer: Analysis of algorithms.

# Defining Efficiency

# Defining Efficiency

Runs fast on typical real-world inputs?

# Defining Efficiency

Runs fast on typical real-world inputs?

## PROS

Enough in practice

Easier to satisfy

# Defining Efficiency

Runs fast on typical real-world inputs?

| PROS               | CONS                               |
|--------------------|------------------------------------|
| Enough in practice | Hard to quantify                   |
| Easier to satisfy  | Exceptions matter!                 |
|                    | “Real-world”<br>is a moving target |

# Efficiency

**Want a general theory of efficiency that is**

# Efficiency

**Want a general theory of efficiency that is**

**I. Simple (mathematically)**

# Efficiency

**Want a general theory of efficiency that is**

- 1. Simple (mathematically)**
- 2. Objective (doesn't depend on i5 vs i7 processor)**

# Efficiency

**Want a general theory of efficiency that is**

- 1. Simple (mathematically)**
- 2. Objective (doesn't depend on i5 vs i7 processor)**
- 3. Captures scalability (input-sizes change)**

# Efficiency

**Want a general theory of efficiency that is**

- 1. Simple (mathematically)**
- 2. Objective (doesn't depend on i5 vs i7 processor)**
- 3. Captures scalability (input-sizes change)**
- 4. Predictive of practical performance**
  - “theoretically bad” algorithms should be bad in practice and vice versa (usually)

# Measuring efficiency

**Most important resource in computing:**

# Measuring efficiency

**Most important resource in computing: TIME**

# Measuring efficiency

**Most important resource in computing: TIME**

**TIME:** # of instructions executed in a simple programming language

# Measuring efficiency

**Most important resource in computing: TIME**

**TIME:** # of instructions executed in a simple programming language

- Only simple operations (+,\*,-,=,if,call,...)

# Measuring efficiency

**Most important resource in computing: TIME**

**TIME:** # of instructions executed in a simple programming language

- Only simple operations (+,\*,-,=,if,call,...)
- Each operation takes one time step

# Measuring efficiency

**Most important resource in computing: TIME**

**TIME:** # of instructions executed in a simple programming language

- Only simple operations (+,\*,-,=,if,call,...)
- Each operation takes one time step
- Each memory access takes one time step

# Measuring efficiency

Most important resource in computing: **TIME**

**TIME:** # of instructions executed in a simple programming language

- Only simple operations (+,\*,-,=,if,call,...)
- Each operation takes one time step
- Each memory access takes one time step
- No fancy stuff built in (add these two matrices, copy this long string,...)

# We left out things but...

## Things we've dropped

- memory hierarchy

  - disk, caches, registers have many orders of magnitude differences in access time

- not all instructions take the same time in practice (+, ÷)

- communication

- different computers have different primitive instructions

## However,

  - one can usually tune implementations so that the hierarchy, etc., is not a huge factor

# Problem

- Algorithms can have different running times on different inputs.
- Smaller inputs take less time, larger inputs take more time.

# Solution

Measure performance on input size  $n$

# Solution

Measure performance on input size  $n$

**Average-case complexity:** *Average* # steps  
algorithm takes on inputs of size  $n$

# Solution

Measure performance on input size  $n$

**Average-case complexity:** *Average #* steps algorithm takes on inputs of size  $n$

**Worst-case complexity:** *Max #* steps algorithm takes over all inputs of size  $n$

# Pros and cons:

## Average-case

- Over what probability distribution? (different people may have different “average” problems)
- Analysis often hard

## Worst-case

- + A fast algorithm has a comforting guarantee
- + Analysis easier than average-case
- + Useful in real-time applications (space shuttle, nuclear reactors)
- May be too pessimistic

Best-case ...

# Best-case ...

Characterize *growth-rate* of (worst-case) run time as a function of problem size, up to a constant factor

# Best-case ...

Characterize *growth-rate* of (worst-case) run time as a function of problem size, up to a constant factor

Why not try to be more precise?

- Technological variations (computer, compiler, OS, ...) easily 10x or more

# Complexity

The *complexity* of an algorithm associates a number  $T(n)$  with each problem size  $n$ :

$T(n)$  = worst-case time taken on problems of size  $n$ .

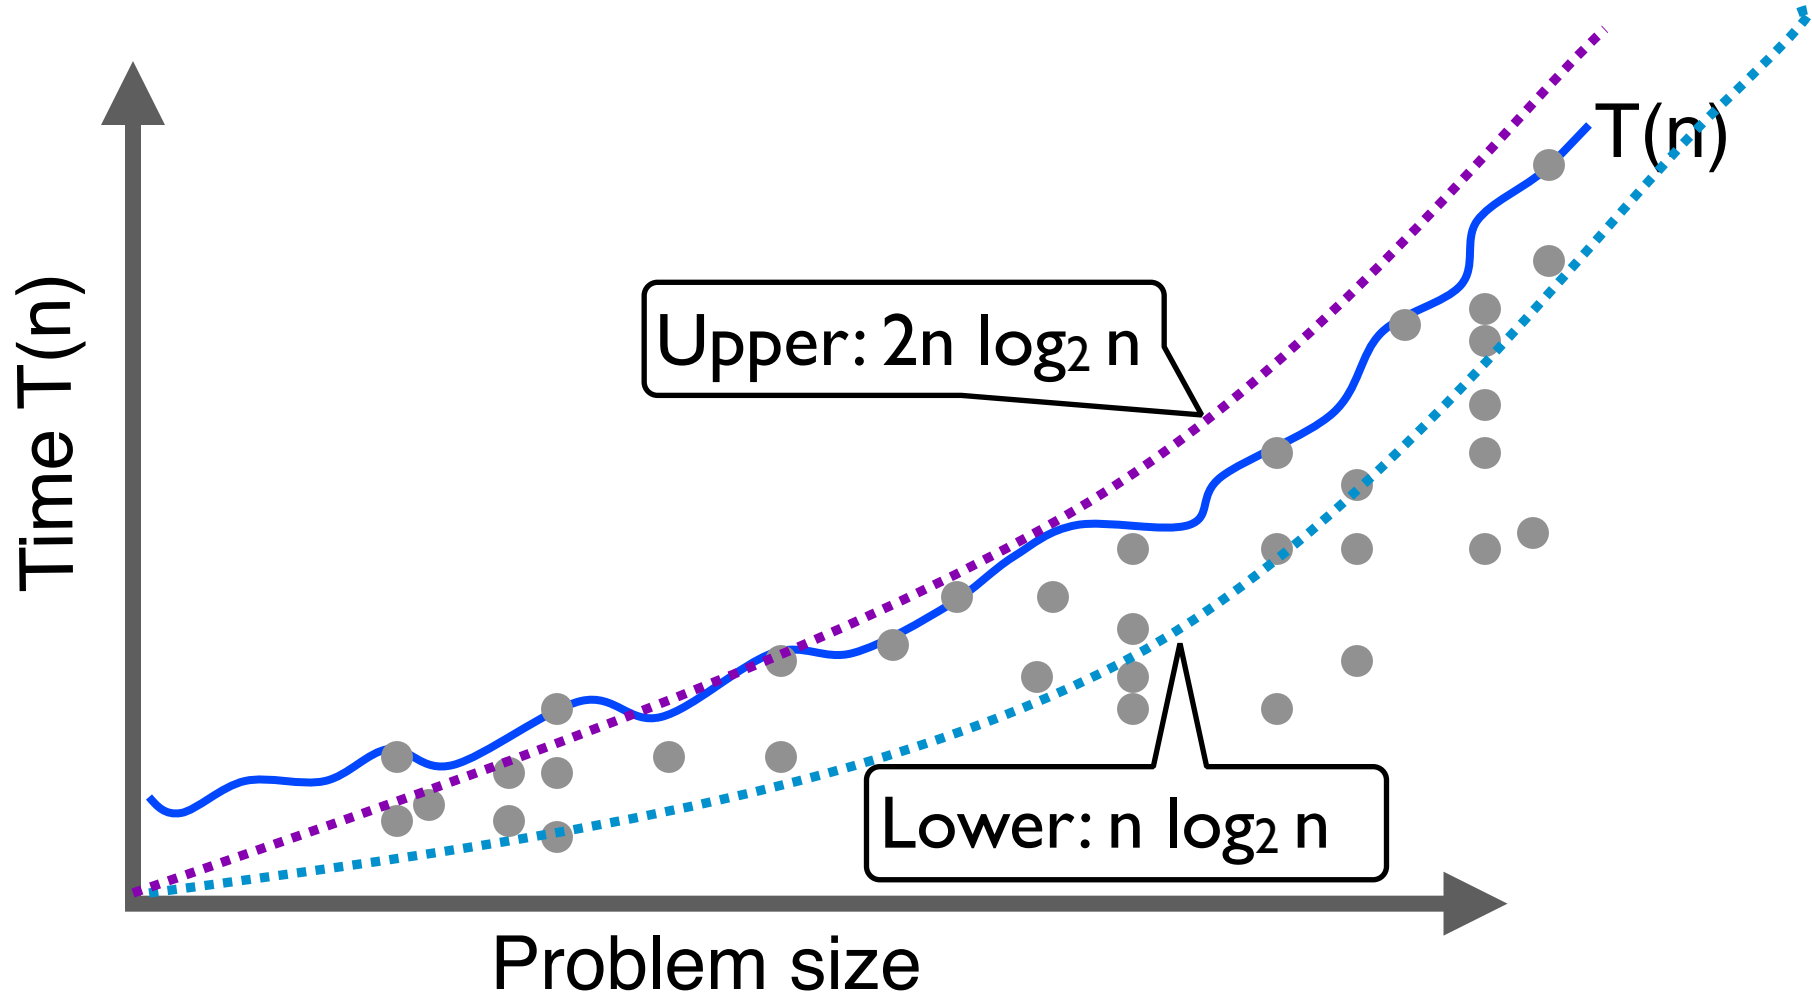

Mathematically:  $T : \mathbb{N} \rightarrow \mathbb{R}^+$

i.e.,  $T$  is a function that maps positive integers (problem sizes) to positive real numbers (number of steps).

# Complexity

# Complexity

# Asymptotic analysis

Methodology for comparing run-times

# Asymptotic analysis

Methodology for comparing run-times

Given two functions  $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$

# Asymptotic analysis

Methodology for comparing run-times

Given two functions  $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$

$f(n) = O(g(n))$ : iff there is a constant  $c > 0$  so that  
 $f(n)$  is eventually-always at most  $c g(n)$

# Asymptotic analysis

Methodology for comparing run-times

Given two functions  $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$

$f(n) = O(g(n))$ : iff there is a constant  $c > 0$  so that  
 $f(n)$  is eventually-always **at most**  $c g(n)$

$f(n) = \Omega(g(n))$ : iff there is a constant  $c > 0$  so that  
 $f(n)$  is eventually-always **at least**  $c g(n)$

# Asymptotic analysis

Methodology for comparing run-times

Given two functions  $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$

$f(n) = O(g(n))$ : iff there is a constant  $c > 0$  so that  
 $f(n)$  is eventually-always **at most**  $c g(n)$

$f(n) = \Omega(g(n))$ : iff there is a constant  $c > 0$  so that  
 $f(n)$  is eventually-always **at least**  $c g(n)$

$f(n) = \Theta(g(n))$ : iff both hold - there are constants  $c_1, c_2 > 0$  so that eventually always  $c_1 g(n) < f(n) < c_2 g(n)$

# Examples

$10n^2 - 16n + 100$  is  $O(n^2)$

$10n^2 - 16n + 100 < 10n^2$  for all  $n > 10$

$10n^2 - 16n + 100$  is  $\Omega(n^2)$

$10n^2 - 16n + 100 > n^2$  for all  $n > 10$

Therefore also  $10n^2 - 16n + 100$  is  $\Theta(n^2)$

$10n^2 - 16n + 100$  is not  $O(n)$  also not  $\Omega(n^3)$

# Big-Theta, etc. not always “nice”

$$f(n) = \begin{cases} n^2, & n \text{ even} \\ n, & n \text{ odd} \end{cases}$$

$f(n)$  is not  $\Theta(n^a)$  for any  $a$ .

Fortunately, such nasty cases are rare

# Polynomial time

P: Running time is  $O(n^d)$  for some constant  $d$  independent of the input size  $n$ .

**NICE SCALING:** Doubling problem-size, increases time by a constant factor  $c$  (e.g.,  $c \sim 2^d$ )

Contrast with exponential: Doubling problem-size can square the run-time!

(e.g.,  $T(n) = 2^{n/10}$  vs  $T(2n) = 2^{2(n/10)} = T(n)^2$ )

# Polynomial time

P: Running time is  $O(n^d)$  for some constant  $d$  independent of the input size  $n$ .

Behaves well under composition: if algorithm has a polynomial running time with polynomial number of calls to a subroutine with polynomial running time, then overall running time is still polynomial.

# polynomial vs exponential growth

# Why It Matters

**Table 2.1** The running times (rounded up) of different algorithms on inputs of increasing size, for a processor performing a million high-level instructions per second. In cases where the running time exceeds  $10^{25}$  years, we simply record the algorithm as taking a very long time.

|                 | $n$     | $n \log_2 n$ | $n^2$   | $n^3$        | $1.5^n$      | $2^n$           | $n!$            |
|-----------------|---------|--------------|---------|--------------|--------------|-----------------|-----------------|
| $n = 10$        | < 1 sec | < 1 sec      | < 1 sec | < 1 sec      | < 1 sec      | < 1 sec         | 4 sec           |
| $n = 30$        | < 1 sec | < 1 sec      | < 1 sec | < 1 sec      | < 1 sec      | 18 min          | $10^{25}$ years |
| $n = 50$        | < 1 sec | < 1 sec      | < 1 sec | < 1 sec      | 11 min       | 36 years        | very long       |
| $n = 100$       | < 1 sec | < 1 sec      | < 1 sec | 1 sec        | 12,892 years | $10^{17}$ years | very long       |
| $n = 1,000$     | < 1 sec | < 1 sec      | 1 sec   | 18 min       | very long    | very long       | very long       |
| $n = 10,000$    | < 1 sec | < 1 sec      | 2 min   | 12 days      | very long    | very long       | very long       |
| $n = 100,000$   | < 1 sec | 2 sec        | 3 hours | 32 years     | very long    | very long       | very long       |
| $n = 1,000,000$ | 1 sec   | 20 sec       | 12 days | 31,710 years | very long    | very long       | very long       |

not only get very big, but do so *abruptly*, which likely yields erratic performance on small instances

## another view of poly vs exp

Next year's computer will be 2x faster. If I can solve problem of size  $n_0$  today, how large a problem can I solve in the same time next year?

| Complexity | Increase                          | E.g. $T = 10^{12}$                     |
|------------|-----------------------------------|--|
| $O(n)$     | $n_0 \rightarrow 2n_0$            | $10^{12} \rightarrow 2 \times 10^{12}$ |
| $O(n^2)$   | $n_0 \rightarrow \sqrt{2} n_0$    | $10^6 \rightarrow 1.4 \times 10^6$     |
| $O(n^3)$   | $n_0 \rightarrow \sqrt[3]{2} n_0$ | $10^4 \rightarrow 1.25 \times 10^4$    |
| $2^{n/10}$ | $n_0 \rightarrow n_0 + 10$        | $400 \rightarrow 410$                  |
| $2^n$      | $n_0 \rightarrow n_0 + 1$         | $40 \rightarrow 41$                    |

# Summary

Typical initial goal for algorithm analysis is to find a

reasonably tight

i.e.,  $\Theta$  if possible

*asymptotic*

i.e.,  $O$  or  $\Theta$

bound on

usually upper bound

*worst case* running time

as a function of problem size

This is rarely the last word, but often helps separate good algorithms from blatantly bad ones - so you can concentrate on the good ones!

# Complexity of multiplication

| Multiplication                                   |
|--|
| <b>INPUT:</b> Two $n$ -digit numbers $a, b$      |
| <b>OUTPUT:</b> $(a \times b)$ in decimal format. |

# Complexity of multiplication

| Multiplication  |
|---|
| <b>INPUT:</b> Two $n$ -digit numbers $a, b$<br><b>OUTPUT:</b> $(a \times b)$ in decimal format. |

How efficient is grade-school algorithm?

Grade-school algorithm takes  $O(n^2)$  time.

# Divide-and-conquer paradigm

---

## Divide-and-conquer.

- Divide problem into several subproblems.
- Solve each subproblem recursively.
- Combine solutions to subproblems into overall solution.

# Divide-and-conquer paradigm

---

## Divide-and-conquer.

- Divide problem into several subproblems.
- Solve each subproblem recursively.
- Combine solutions to subproblems into overall solution.

# Divide-and-conquer paradigm

---

## Divide-and-conquer.

- Divide problem into several subproblems.
- Solve each subproblem recursively.
- Combine solutions to subproblems into overall solution.

## Most common usage.

- Divide size  $n$  into **two** subproblems of size  $n/2$  in **linear time**.
- Solve two subproblems recursively.
- Combine two solutions into overall solution in **linear time**.

**RUN-TIME =  $O(n \log n)$ !**

# Sorting problem

**Problem.** Given a list of  $n$  elements from a totally-ordered universe, rearrange them in ascending order.

|    | Name                          | Artist            | Time | Album   |

# Mergesort

- Divide array into two halves.
- Recursively sort left half.
- Recursively sort right half.
- Merge two halves to make sorted whole.

Master theorem

# Plan for Today

Divide and Conquer

Merge-sort

**Master theorem:** Generic method for solving recurrences.

# Master method

**Goal:** Solve common divide-and-conquer recurrences:

$$T(n) = a T\left(\frac{n}{b}\right) + f(n)$$

# Master method

**Goal:** Solve common divide-and-conquer recurrences:

$$T(n) = a T\left(\frac{n}{b}\right) + f(n)$$

**Terms.**

# Master method

**Goal:** Solve common divide-and-conquer recurrences:

$$T(n) = a T\left(\frac{n}{b}\right) + f(n)$$

**Terms.**

- $a \geq 1$  is the number of subproblems.

# Master method

**Goal:** Solve common divide-and-conquer recurrences:

$$T(n) = a T\left(\frac{n}{b}\right) + f(n)$$

**Terms.**

- $a \geq 1$  is the number of subproblems.
- $b > 0$  is the factor by which subproblem size decreases.

# Master method

**Goal:** Solve common divide-and-conquer recurrences:

$$T(n) = a T\left(\frac{n}{b}\right) + f(n)$$

**Terms.**

- $a \geq 1$  is the number of subproblems.
- $b > 0$  is the factor by which subproblem size decreases.
- $f(n)$  = work to divide/merge subproblems.
